ABSTRACT

Cooperative Drone Swarm Search and Rescue using Multi-Agent Reinforcement Learning and Swarm-Based Agent Simulation proposes an intelligent system for autonomous search and rescue operations using multiple cooperative drones. Traditional search methods and single-drone systems often face limitations such as limited area coverage, inefficient coordination, redundant exploration, and increased search time.

The proposed system integrates Multi-Agent Reinforcement Learning (MARL) with swarm-based simulation, allowing multiple drones to communicate, coordinate, and learn suitable actions for efficient navigation and target detection. Each drone operates as an independent learning agent while cooperating with other drones to maintain safe movement, avoid redundant exploration, and maximize search coverage. Swarm coordination is achieved using separation, cohesion, and alignment mechanisms.

The project consists of data generation and statistical analysis, data preprocessing, multi-agent drone swarm simulation, MARL-based training, and performance evaluation. The learning system uses reward-based decision-making to encourage target detection and search coverage while penalizing collisions and unnecessary energy consumption.

The system was evaluated using performance measures including average reward, maximum reward, average steps, final distance, and success rate. The trained drone swarm achieved an average reward of 217.86, maximum reward of 378.18, average steps of 15.50, final distance of 0.00, and a 100% success rate. The simulation also achieved an average final distance of 3.77 and a total reward of 601.12 for the configured simulation. These results demonstrate effective cooperative navigation and successful target reaching.

Overall, the proposed framework demonstrates the potential of combining MARL with swarm-based coordination for improving autonomous search and rescue operations.

CHAPTER 1

INTRODUCTION AND ENGINEERING PROBLEM

1.1 Background

Search and rescue operations often require quick and efficient exploration of large or unknown areas. Traditional search methods and single-drone systems may provide limited coverage and require more time to locate targets.

Cooperative drone swarms provide an effective approach by using multiple autonomous drones that can work together to explore an environment. Multi-Agent Reinforcement Learning (MARL) enables multiple drones to learn and make decisions collaboratively, while swarm-based agent simulation supports coordination, communication, collision avoidance, and collective movement.

In the proposed system, each drone acts as an independent learning agent and selects suitable actions according to its current state and surrounding environment. Separation, cohesion, and alignment mechanisms are used to maintain safe and coordinated swarm movement. A cooperative reward system encourages search coverage and target detection while penalizing collisions and excessive energy consumption.

1.2 Need for the Project

Existing single-drone and conventional search approaches may suffer from:

Limited search area coverage

Inefficient path planning

Redundant exploration

Poor coordination between drones

Increased search time

Unnecessary movement and energy consumption

When multiple drones operate without proper cooperation, they may repeatedly search the same areas or move inefficiently. Therefore, an intelligent cooperative system is required to coordinate multiple drones, maximize search coverage, improve target detection, and reduce unnecessary movement and energy consumption.

1.3 Problem Statement

Existing search and rescue systems and single-drone approaches suffer from limited coverage, inefficient coordination, redundant exploration, poor path planning, and increased search time.

Therefore, there is a need for an intelligent cooperative drone swarm system using Multi-Agent Reinforcement Learning and swarm-based agent simulation to improve coordination, maximize search area coverage, optimize navigation, improve target detection, and enhance search and rescue efficiency.

1.4 Project Aim

To develop an intelligent cooperative drone swarm system using Multi-Agent Reinforcement Learning and swarm-based agent simulation for autonomous search and rescue operations, with improved coordination, search coverage, target detection, and navigation efficiency.

1.5 Project Objectives

To develop a cooperative drone swarm system using Multi-Agent Reinforcement Learning (MARL) for autonomous search and rescue operations.

To implement swarm-based coordination for efficient communication, task allocation, path planning, and maximum search area coverage among multiple drones.

To improve target detection accuracy, reduce search time, and enhance the overall efficiency and reliability of cooperative drone swarm missions.

1.6 Scope

Included

Cooperative multi-drone search and rescue simulation

Multi-Agent Reinforcement Learning

Swarm coordination

Drone state representation

Target detection

Search coverage evaluation

Reward-based learning

Drone movement simulation

Performance evaluation

Statistical analysis and visualization

Excluded / Current Boundary

The current project is based on a simulation environment and does not demonstrate deployment on physical drones or a real-world search-and-rescue mission.

The current implementation uses configurable simulation parameters such as the number of drones, simulation steps, target coordinates, grid size, learning rate, discount factor, and exploration rate.

1.7 Expected Engineering Outcome

The expected outcome is an intelligent multi-agent drone swarm simulation capable of:

Cooperative navigation

Target reaching

Improved search coverage

Target detection

Coordinated swarm movement

Reward-based learning

Performance evaluation using quantitative metrics

The developed system demonstrates successful target reaching with a 100% success rate and final distance of 0.00 in the reported trained-drone evaluation.

CHAPTER 2

LITERATURE REVIEW AND EXISTING SOLUTIONS

2.1 Review Method

The literature survey considered research related to:

Multi-Agent Reinforcement Learning

Deep Reinforcement Learning

UAV search and rescue

Multi-UAV coordination

Swarm robotics

UAV communication

Cooperative path planning

Autonomous target search and tracking

2.2 Review of Existing Work

1. Hickling et al. (2026)

Paper: Deep Reinforcement Learning Based Autonomous Decision-Making for Cooperative Uncrewed Aerial Vehicles: A Search and Rescue Real World Application

The study developed a deep reinforcement learning framework for cooperative UAVs supporting autonomous navigation, task allocation, and victim search in real-world search-and-rescue missions.

2. Chen et al. (2026)

Paper: Multi-stage Hierarchical Multi-Agent Reinforcement Learning for UAV-Quadraped Completing Search and Rescue

The research proposed a hierarchical MARL architecture allowing UAVs and ground robots to cooperate during search-and-rescue operations, improving coordination and exploration.

3. Liu et al. (2024)

Paper: A Two-Stage Target Search and Tracking Method for UAV Based on Deep Reinforcement Learning

The research introduced a two-stage deep reinforcement learning method for UAV target search and tracking, improving navigation accuracy and target-following performance.

4. Sadhu et al. (2024)

Paper: Aerial-Deep Search: Distributed Multi-Agent Deep Reinforcement Learning for Search Missions

The work presented a distributed multi-agent deep reinforcement learning framework that allows multiple UAVs to cooperate while exploring unknown environments.

5. Han et al. (2024)

Paper: Joint Association, Deployment and Flight Trajectory Optimization for Multi-UAV Enabled Large-Scale Mobile Edge Computing

The research focused on optimized UAV deployment and trajectory planning to improve communication efficiency and cooperative mission performance.

2.3 Comparative Analysis

Existing Approach	Advantages	Limitations / Gap	Relevance
Single-drone search	Simple operation	Limited coverage and increased search time	Motivates multi-drone approach
Deep RL-based UAV search	Autonomous decision-making	Primarily focuses on individual/cooperative UAV learning	Supports RL-based navigation
Hierarchical MARL	Improved multi-agent coordination	More complex architecture	Supports MARL cooperation
Distributed MARL	Cooperative exploration	Requires coordination and information sharing	Closely related to proposed system
Swarm robotics	Decentralized collective behaviour	Coordination mechanisms required	Supports swarm-based movement
UAV trajectory optimization	Improved path planning	Focus may be application-specific	Supports optimized drone movement

2.4 Research / Engineering Gap

The reviewed studies demonstrate the usefulness of reinforcement learning, multi-agent cooperation, UAV coordination, swarm intelligence, and path planning.

The proposed project brings these concepts together in a cooperative drone swarm simulation by integrating MARL with swarm-based coordination, including separation, cohesion, alignment, information sharing, reward-based learning, and performance evaluation.

2.5 Proposed Contribution

The project proposes a cooperative drone swarm framework in which multiple drones operate as learning agents while coordinating their movement through swarm-based mechanisms.

The framework focuses on:

- Cooperative navigation
- Search area coverage
- Target detection
- Swarm coordination
- Collision avoidance
- Reward-based learning
- Performance evaluation

The architecture connects the search environment, MARL module, swarm coordination module, optimized drone movement, and performance evaluation.

CHAPTER 3

ENGINEERING DESIGN & TRADE-OFFS, SUSTAINABILITY, ETHICS, SAFETY, RISK & SECURITY

3.1 Requirements

Stakeholder / User Requirements

The proposed system is designed to support autonomous search and rescue operations using multiple cooperative drones. The main requirements are efficient exploration of large or unknown search areas, improved coordination among drones, reduced redundant exploration, faster target detection, and effective target reaching. The simulation user should also be able to configure important parameters such as the number of drones, simulation steps, target coordinates, training episodes, grid size, learning rate, discount factor, and exploration rate.

Stakeholder	Requirement
Search and Rescue Operation	Efficient exploration of large or unknown search areas
Simulation User	Configure the number of drones, simulation steps, and target coordinates
Drone Swarm	Coordinate movement and share relevant information among neighbouring drones
Reinforcement Learning System	Enable drones to learn suitable actions for cooperative navigation
Mission Evaluation	Evaluate search performance using reward, steps, final distance, and success rate

Functional & Non-Functional Requirements

Requirement	Type (Functional/Non-Functional)	Measurable Target
Simulate multiple autonomous drones	Functional	Multiple drones operate within the search environment
Configure drone swarm	Functional	Number of drones can be configured
Configure search environment	Functional	Search area, obstacles, and target locations can be defined
Coordinate drone movement	Functional	Separation, cohesion, and alignment mechanisms are applied

Share relevant information	Functional	Drones share information with neighbouring drones
Apply MARL	Functional	Each drone acts as an independent learning agent
Calculate cooperative reward	Functional	Coverage, target detection, collision and energy components are considered
Detect and reach target	Functional	Target detection and target-reaching performance are recorded
Measure search performance	Functional	Reward, search steps, final distance, and success rate are evaluated
Support configurable training	Functional	Training episodes, grid size, learning rate, discount factor, and exploration rate can be configured
Reduce redundant exploration	Non-Functional	Cooperative movement should minimize repeated exploration
Improve search efficiency	Non-Functional	Search time and unnecessary movement should be reduced
Maintain safe swarm movement	Non-Functional	Collision avoidance is supported through swarm coordination
Scalability	Non-Functional	The system supports a configurable number of drones
Reliable evaluation	Non-Functional	Performance is evaluated using defined simulation metrics

The functional and non-functional requirements are derived from the project's stated methodology, configurable simulation parameters, swarm coordination mechanism, MARL approach, and performance evaluation metrics.

3.2 Constraints & Applicable Standards

The current project is implemented as a swarm-based simulation rather than a physical drone deployment. Therefore, the design is constrained by the simulation environment and the parameters used for training and evaluation. The number of drones, simulation steps, target coordinates, grid size, training episodes, learning rate, discount factor, and exploration rate can be configured.

The project sources do not identify a specific engineering standard or regulatory code that was applied to the implemented simulation. Therefore, no specific standard is claimed here.

Standard / Code	Requirement	How Applied in This Project
No specific standard	No specific engineering or	The project is implemented and evaluated

identified in the project sources	regulatory standard is stated	as a simulation-based cooperative drone swarm system
-----------------------------------	-------------------------------	--

The major technical constraints identified from the project are the dependence on simulation parameters and the difference between simulated drone behaviour and real-world drone operation. The future scope specifically identifies the need for more realistic collision avoidance, communication, energy constraints, larger areas, dynamic obstacles, and real-world datasets.

3.3 Design Specifications

The design specifications are based on the system architecture, proposed methodology, configurable simulation parameters, drone state representation, swarm coordination mechanism, and evaluation measures described in the project.

Parameter	Target/Requirement	Unit	Priority
Number of drones	Configurable multiple drones	Number of drones	High
Search environment	Predefined search area	Search area	High
Obstacles	Included in the environment	Position	High
Target locations	Configurable target coordinates	Coordinates	High
Drone position	$P_i(t) = (x_i, y_i)$	Coordinates	High
Drone velocity	Maintained during simulation	Velocity	Medium
Battery level	Included in drone state	Battery level	Medium
Sensor range	Defined for each drone	Range	Medium
Local observation	Available to each drone	State information	High
Learning rate	Configurable	α	High
Discount factor	Configurable	γ	High
Exploration rate	Configurable	Rate	Medium
Search coverage	Maximize explored area	Percentage	High
Target detection	Maximize detected targets	Percentage	High
Collision	Minimize collision occurrence	Count	High
Energy consumption	Minimize unnecessary consumption	Energy	Medium
Final distance	Minimize distance to target	Distance	High
Success rate	Maximize successful target reaching	Percentage	High

The drone state includes position, velocity, battery level, sensor range, and local observation. The system also uses separation, cohesion, and alignment forces for coordinated swarm movement.

3.4 Alternative Solutions & Evaluation

Alternative 1: Single-Drone Search

A single-drone approach performs the search using one autonomous drone. It provides a simpler search process but has limited coverage and can require more time for large or unknown search areas.

Alternative 2: Conventional Multi-Drone Search

A conventional multi-drone approach uses multiple drones to explore the environment. It can provide wider exploration, but without suitable cooperative learning and coordination, drones may perform redundant exploration or move inefficiently.

Alternative 3: MARL-Based Cooperative Drone Swarm

The proposed approach combines multiple autonomous drones with Multi-Agent Reinforcement Learning and swarm-based coordination. Each drone acts as an independent learning agent while separation, cohesion, alignment, information sharing, and cooperative rewards support coordinated navigation and search.

The original project sources do not provide numerical weights or numerical ratings for the alternatives. Therefore, no artificial weighting or scoring values are introduced below.

Criterion	Weight	Alternative 1	Alternative 2	Alternative 3
Performance	Not specified	Limited by single drone	Improved through multiple drones	Improved through MARL and cooperation
Cost	Not specified	Single-drone system	Multiple drones	Multiple simulated learning agents
Safety	Not specified	Individual movement	Requires coordination	Collision avoidance through swarm coordination
Sustainability	Not specified	Limited cooperative optimization	Depends on coordination	Energy consumption included in reward
Reliability	Not specified	Limited coverage	Dependent on coordination	Learning and cooperative behaviour support mission performance

Based on the documented project approach, Alternative 3 is selected because it directly addresses the identified limitations of single-drone and conventional search approaches by combining MARL with swarm-based coordination.

3.5 Selected Design & Detailed Design

The selected design is the Cooperative Drone Swarm Search and Rescue system using Multi-Agent Reinforcement Learning and Swarm-Based Agent Simulation. The selection is based on the requirement to improve coordination, maximize search coverage, reduce redundant exploration, improve target detection, and reduce search time. The project integrates multiple autonomous drones, MARL, swarm coordination, and cooperative reward calculation into a single simulation framework.

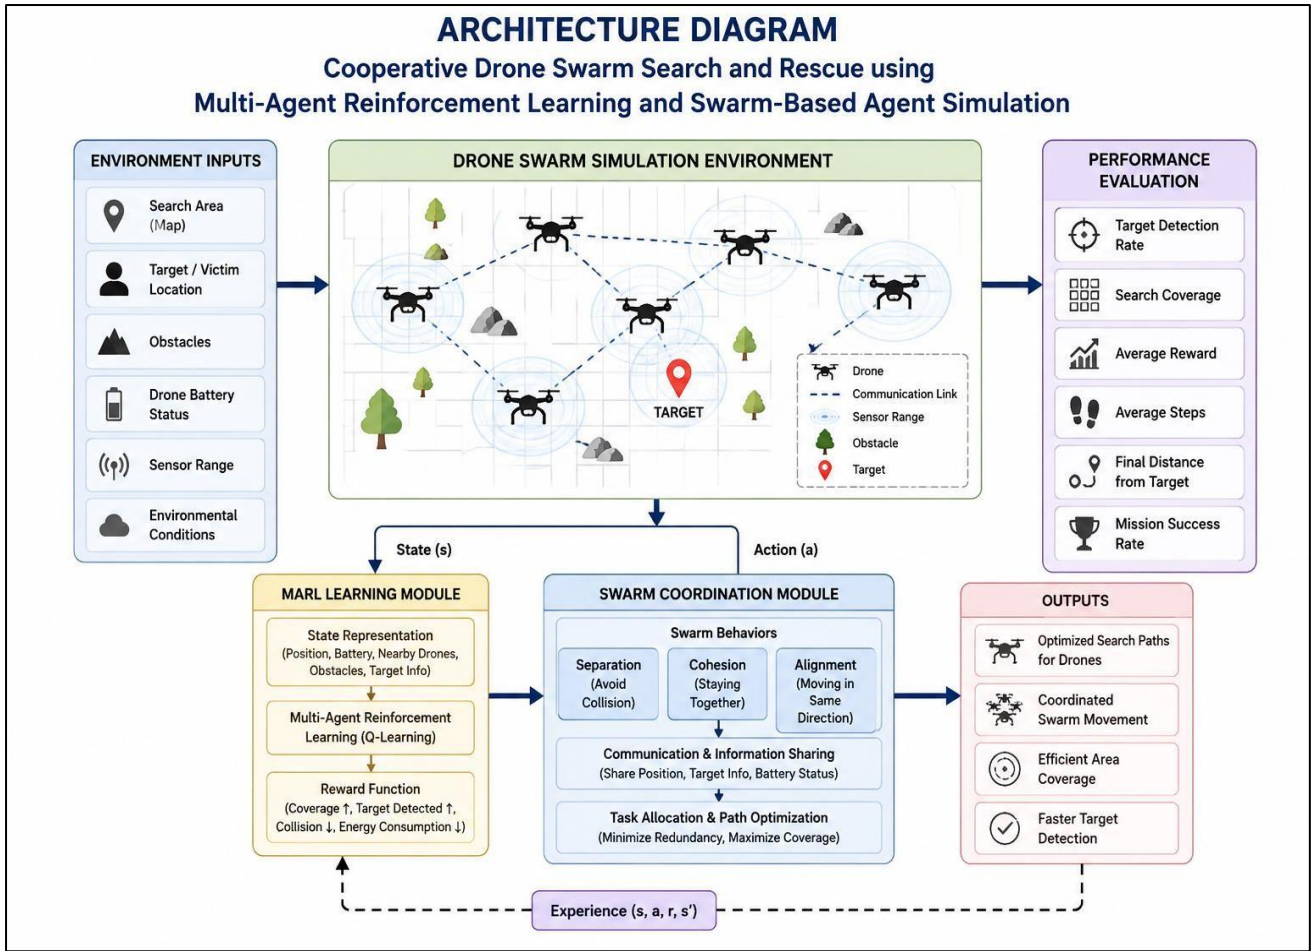

Figure 3.1: Cooperative Drone Swarm Search and Rescue Architecture

The architecture consists of the search environment, drone swarm, MARL module, swarm coordination mechanism, and performance evaluation. The search environment provides information to the drone swarm for exploration. The MARL module enables drones to select suitable actions based on their current state and rewards, while the swarm coordination module supports separation, cohesion, alignment, and information sharing. The system generates search paths and evaluates performance using coverage, target detection, reward, and success rate.

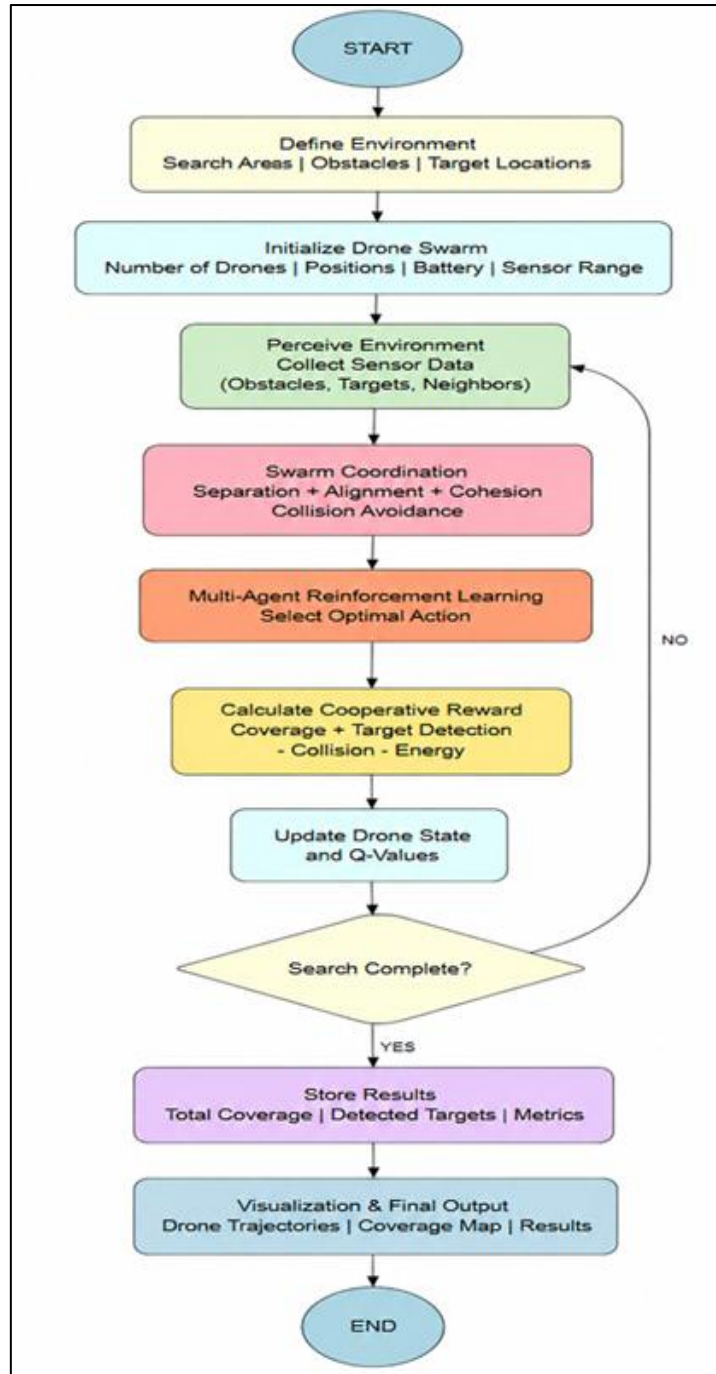

Figure 3.2: Proposed Methodology Flowchart

Define Environment → Initialize Drone Swarm → Swarm Coordination & MARL → Reward & State Update → Search & Output

The methodology begins by defining the search environment, including the search area, obstacles, and target locations. The drone swarm is then initialized with parameters such as the number of drones, positions, battery, and sensor range. Swarm coordination and MARL are applied to select suitable actions, after which rewards and drone states are updated. The process is repeated until completion, after which the trajectories, coverage map, and performance results are produced.

The main design components are described below.

The search environment represents a predefined search area containing obstacles and target locations. It provides the environment in which the drones perform cooperative exploration.

Each drone is represented as an independent learning agent. Its state includes position $P_i(t) = (x_i, y_i)$, velocity $V_i(t)$, battery $B_i(t)$, sensor range R_i , and local observation $O_i(t)$. Each drone receives local environmental information and shares relevant information with neighbouring drones.

The swarm coordination mechanism controls cooperative drone movement using separation, cohesion, and alignment forces. Separation supports collision avoidance, cohesion supports collective movement, and alignment supports coordinated swarm behaviour. These mechanisms enable the drones to maintain formation and explore the search region cooperatively.

The MARL module allows each drone to act as an independent learning agent. The agents learn suitable actions through interaction with the environment and update their Q-values using the current state, selected action, reward, next state, learning rate, and discount factor. The learned behaviour supports navigation, target search, and task allocation.

The cooperative reward mechanism encourages desirable swarm behaviour. The reward considers search coverage, target detection, collision penalties, and energy consumption penalties. Therefore, the learning process encourages greater coverage and target detection while reducing collisions and unnecessary energy consumption.

Search coverage is calculated using:

$$\text{Search Coverage (\%)} = (A_{\text{searched}} / A_{\text{total}}) \times 100$$

where A_{searched} represents the area searched by the drone swarm and A_{total} represents the total search area.

Target detection rate is calculated using:

$$\text{Target Detection Rate (\%)} = (N_{\text{detected}} / N_{\text{targets}}) \times 100$$

where N_{detected} represents the number of detected targets and N_{targets} represents the total number of targets. A higher search coverage percentage indicates more effective exploration of the search region.

Systems Approach

The search environment, drone swarm, MARL module, swarm coordination module, and performance evaluation module operate as interconnected parts of the system. The environment provides state information to the drones, while the MARL module uses this information to select suitable actions. The swarm coordination mechanism supports cooperative movement and information sharing between drones. The resulting drone behaviour is evaluated using performance measures such as reward, search

steps, final distance, and success rate.

3.6 Trade-off Analysis

The design decisions involve balancing cooperative performance with system complexity. The following trade-offs are derived from the design choices documented in the project.

Design Decision	Alternative Considered	Benefit	Disadvantage	Final Decision & Justification
Multiple drones	Single-drone search	Wider area can be explored cooperatively	Requires coordination between drones	Multiple drones selected because the project aims to improve coverage and reduce search time
MARL	Conventional movement/search	Enables agents to learn suitable actions	Requires training and parameter configuration	MARL selected to support adaptive cooperative navigation
Swarm coordination	Independent drone movement	Supports formation, collision avoidance, and cooperative exploration	Adds coordination mechanisms	Separation, cohesion, and alignment selected for coordinated swarm behaviour
Cooperative reward	Individual action-based reward	Encourages coverage and target detection while penalizing collisions and energy consumption	Reward calculation is more complex	Cooperative reward selected to align learning with mission objectives
Simulation	Immediate physical deployment	Provides a configurable environment for development and evaluation	Does not represent all real-world conditions	Simulation selected for the current project

The final design therefore prioritizes cooperative search performance, adaptive learning, coordinated movement, and measurable simulation-based evaluation.

3.7 Sustainability, Ethics, Safety, Risk & Security

The project addresses sustainability, safety, and security considerations through the design of the cooperative reward and swarm coordination mechanisms. However, the project sources do not report

a separate experimental evaluation of ethics or cybersecurity mechanisms. Therefore, these areas are presented only to the extent supported by the project design.

Domain	Consideration	Evidence Evaluated	Impact on Final Decision
Sustainability	Reduce unnecessary energy consumption	Energy consumption is included as a penalty in the cooperative reward	The design encourages efficient movement and reduces unnecessary energy consumption
Ethics	Responsible autonomous search behaviour	The current work is a simulation-based system and does not involve human subjects	Ethical evaluation is limited to the simulation context
Health & Safety	Avoid collisions between drones	Separation mechanism is used along with cohesion and alignment	Swarm coordination is included to support safe and coordinated movement
Security	Information sharing between drones	Relevant information is shared among neighbouring drones	Information sharing supports coordination, but specific cybersecurity mechanisms are not implemented in the reported system

The project specifically identifies collision avoidance and energy consumption as important factors in the cooperative reward and swarm coordination design. The future scope also identifies realistic communication, collision avoidance, and energy constraints as areas for further development.

Risk Register

Risk	Likelihood	Severity	Risk Level	Mitigation	Residual Risk
Drone collision during cooperative movement	Not specified in source	Not specified in source	Not specified in source	Use separation force and swarm coordination	Requires further realistic validation
Redundant exploration	Not specified in source	Not specified in source	Not specified in source	Use information sharing and cooperative learning	Reduced through cooperative behaviour
Excessive energy consumption	Not specified in source	Not specified in source	Not specified in source	Include energy consumption penalty in reward	Requires further evaluation under realistic energy constraints

Inefficient navigation	Not specified in source	Not specified in source	Not specified in source	Use MARL to learn suitable actions and paths	Depends on training configuration
Communication limitations	Not specified in source	Not specified in source	Not specified in source	Share relevant information between neighbouring drones	Realistic communication constraints remain future work
Real-world deployment uncertainty	Not specified in source	Not specified in source	Not specified in source	Extend the simulation with realistic environments and constraints	Physical deployment is outside the current implementation

The current project demonstrates the design and evaluation of a cooperative drone swarm in simulation. The project identifies realistic collision avoidance, communication constraints, energy constraints, dynamic obstacles, larger search areas, and real-world datasets as future extensions.

CHAPTER 4

IMPLEMENTATION, TESTING & RESULTS, PROJECT MANAGEMENT

4.1 Experimental Setup

The cooperative drone swarm simulation was performed using multiple drones to evaluate cooperative movement and target-reaching behaviour. The simulation environment consists of multiple drones operating towards a target position. The number of drones, simulation steps, and target coordinates can be configured before starting the simulation.

For the sample simulation, the system was configured with 5 drones and 50 simulation steps. The simulation records include parameters such as drone ID, battery, speed, target distance, and status. The simulation was used to observe the movement of the drones and their ability to reach the target cooperatively.

Iteration	Drone ID	Battery	Speed	Target Distance	Status
1	1	75.18	36.03	31.06	Target Detected
2	2	45.26	60.95	82.45	Searching
3	3	51.84	40.50	47.03	Target Detected
4	4	38.45	80.42	32.87	Target Detected
5	5	46.18	71.23	12.57	Searching

The simulation achieved an average final distance of 3.77 and a total reward of 601.12, indicating effective cooperative movement towards the target.

4.2 Simulation Results

The multi-agent drone swarm simulation demonstrates the cooperative movement of multiple drones towards the target position. The drones operate simultaneously and their movement is visualized to observe the behaviour of the swarm and its ability to reach the target.

The simulation demonstrates that multiple drones can navigate towards a target while operating as a cooperative swarm. The configurable simulation environment allows different numbers of drones, simulation steps, and target coordinates to be used for evaluation.

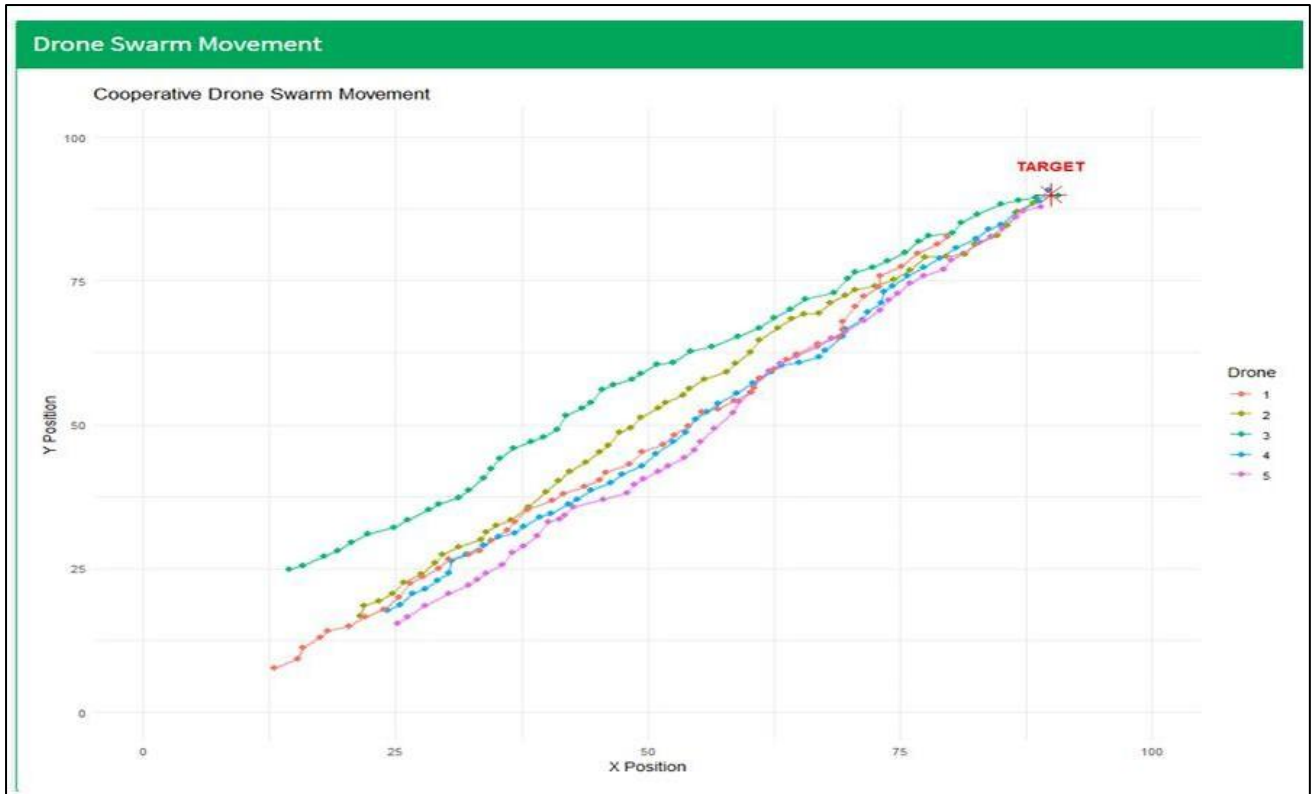

Figure 4.1: Cooperative Drone Swarm Movement Towards the Target

The figure shows the movement paths of five drones as they cooperatively navigate towards the target position. The paths indicate that the drones gradually move closer to the target while maintaining coordinated movement. This demonstrates the effectiveness of the swarm simulation in achieving cooperative navigation and target reaching.

4.3 Multi-Agent Reinforcement Learning Results

The Multi-Agent Reinforcement Learning module was used to train multiple drones for cooperative navigation. The training process allows the agents to learn suitable paths through repeated interaction with the environment.

The training parameters include the number of drones, training episodes, grid size, learning rate, discount factor, and exploration rate. The training reward is analysed to observe the learning performance of the agents.

The trained drone swarm achieved the following performance:

Performance Metric	Value	Observation
Average Reward	217.86	Indicates the overall reward achieved by the agents

Average Steps	15.50	Shows the average number of steps taken to reach the target
Final Distance	0.00	Indicates that the drones reached the target position
Maximum Reward	378.18	Represents the highest reward achieved during training
Success Rate	100%	Shows successful completion of the target-reaching task

The results indicate that the trained drone agents learned effective cooperative navigation behaviour. The final distance of 0.00 and success rate of 100% show that the trained agents successfully reached the target position. The average reward of 217.86 and maximum reward of 378.18 indicate effective learning behaviour, while the average of 15.50 steps shows efficient target navigation.

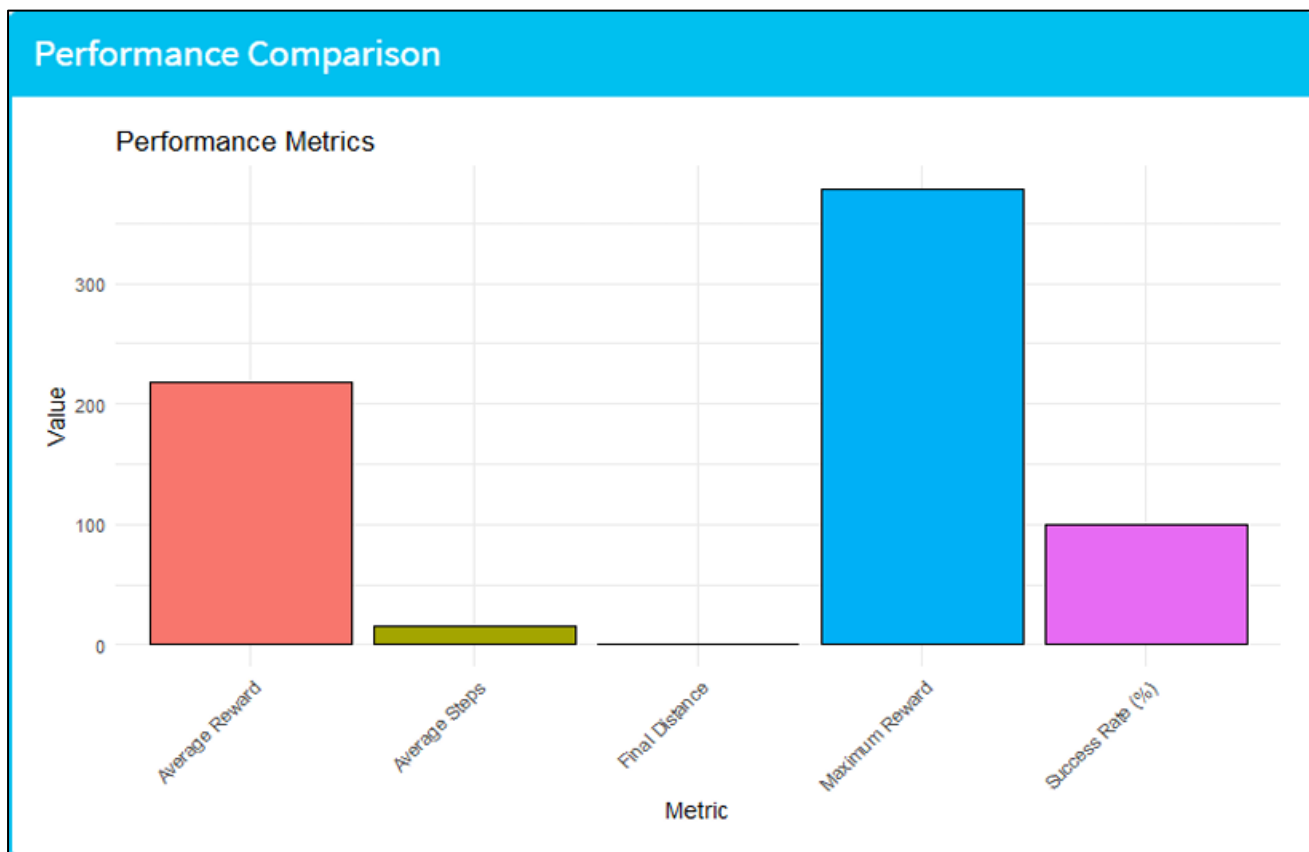

Figure 4.2: Performance Comparison of the Cooperative Drone Swarm

The performance comparison shows that the trained drone agents achieved a 100% success rate with a final distance of 0.00, confirming successful target reaching. The average reward of 217.86 and maximum reward of 378.18 indicate effective learning, while the average of 15.50 steps shows efficient target navigation. Overall, the results demonstrate that the MARL-based approach supports effective cooperative behaviour among drones.

4.4 Performance Evaluation

The performance of the proposed cooperative drone swarm is evaluated using average reward, maximum reward, average steps, final distance, and success rate. These metrics measure the effectiveness of the learned behaviour and the overall performance of the cooperative drone swarm.

Metric	Result	Interpretation
Average Reward	217.86	Shows the overall reward achieved by the trained agents
Maximum Reward	378.18	Shows the highest reward achieved during training
Average Steps	15.50	Indicates the average number of steps required to reach the target
Final Distance	0.00	Indicates successful target reaching
Success Rate	100%	Indicates successful completion of the target-reaching task

The results demonstrate that the MARL-based cooperative drone system is capable of learning effective navigation behaviour. The successful target reaching, high reward values, and reduced number of navigation steps indicate effective cooperative performance.

4.5 Discussion

The simulation and training results demonstrate the effectiveness of combining Multi-Agent Reinforcement Learning with swarm-based agent simulation for cooperative drone navigation. The five-drone simulation produced a total reward of 601.12 and an average final distance of 3.77. The trained swarm achieved an average reward of 217.86, maximum reward of 378.18, average steps of 15.50, final distance of 0.00, and success rate of 100%.

The cooperative movement of the drones demonstrates their ability to navigate towards the target while maintaining coordinated behaviour. The MARL training enables the agents to learn suitable actions through repeated interaction with the environment. The performance results further indicate that the trained agents successfully learned the target-reaching task.

Overall, the results support the proposed approach of integrating MARL with swarm coordination for autonomous search and rescue applications. The system provides cooperative navigation and successful target reaching within the simulated environment.

4.6 Comparison with Existing Approaches

The proposed system addresses limitations identified in traditional search methods, single-drone systems, and approaches without effective cooperation. Single-drone systems may provide limited area coverage and require more time for large or unknown search areas. Multiple drones without suitable cooperation may also perform redundant exploration or move inefficiently.

Approach	Coverage	Coordination	Learning	Target Navigation
Traditional Search	Limited	Limited	No	Conventional
Single-Drone System	Limited	Individual	Limited	Individual navigation
Conventional Multi-Drone	Improved	Requires coordination	Not necessarily adaptive	Cooperative movement
Proposed MARL Drone Swarm	Improved	Cooperative	Yes	Learned cooperative navigation

The proposed MARL-based approach combines multiple learning agents with swarm coordination to support cooperative navigation. The results demonstrate successful target reaching and effective learned behaviour in the simulated environment.

4.7 Summary of Results

The developed system successfully generated drone swarm data, performed preprocessing, simulated cooperative drone movement, trained multiple agents using MARL, and evaluated their performance. The simulation with five drones demonstrated cooperative movement towards the target, while the trained swarm achieved a 100% success rate and a final distance of 0.00.

The average reward of 217.86, maximum reward of 378.18, and average steps of 15.50 demonstrate effective learning and target navigation. The results show the potential of combining Multi-Agent Reinforcement Learning with swarm-based coordination for autonomous search and rescue operations.

CHAPTER 5

CONCLUSION, FUTURE WORK AND REFLECTION

5.1 Conclusion

The project developed a cooperative drone swarm system for autonomous search and rescue using Multi-Agent Reinforcement Learning (MARL) and swarm-based agent simulation. The system combines multiple independent learning agents with swarm coordination to support cooperative navigation, target detection, search coverage, and safe movement. The methodology included drone data generation and preprocessing, multi-agent swarm simulation, MARL training, and performance evaluation.

The simulation demonstrated effective cooperative movement of the drone agents toward the target. The trained system achieved an average reward of 217.86, maximum reward of 378.18, average steps of 15.50, final distance of 0.00, and a success rate of 100%. These results indicate that the proposed MARL-based approach successfully supports cooperative navigation and target reaching.

Overall, the project demonstrates the potential of combining MARL with swarm-based coordination for improving autonomous search and rescue operations. The approach provides cooperative behaviour among multiple drones while reducing redundant exploration and supporting efficient target navigation.

5.2 Future Work

The future development of the project can focus on improving the MARL algorithms and using real-world drone and environmental datasets to achieve more realistic cooperative decision-making. The system can also be extended to more complex search environments containing multiple targets, dynamic obstacles, larger search areas, and realistic collision avoidance, communication, and energy constraints.

Further work can include deploying and comparing the trained system in real-time drone simulation environments with other reinforcement learning and swarm intelligence algorithms. This would provide a broader evaluation of the effectiveness of the proposed cooperative drone swarm approach.

5.3 Professional Learning & Individual Reflection

New Knowledge Acquired

- Understanding of Multi-Agent Reinforcement Learning for cooperative decision-making.
- Understanding of swarm-based coordination among multiple autonomous drones.
- Knowledge of drone state representation, including position, velocity, battery and sensor-related information.

- Experience with reward-based learning for target detection, search coverage, collision reduction and energy efficiency.
- Understanding of performance evaluation using reward, search steps, final distance and success rate.

Engineering & Professional Skills Developed

- Problem formulation for autonomous search and rescue systems.
- Design of multi-agent simulation and cooperative navigation.
- Data generation, preprocessing and analysis.
- Reinforcement learning model implementation and evaluation.
- Interpretation of simulation results and performance metrics.
- Team-based project development, documentation and technical presentation.

Individual Reflection – K. Sri Lasya (192472216)

This project provided practical understanding of cooperative drone navigation and swarm-based simulation. A key learning experience was understanding how multiple drones can share information and coordinate their movement while independently learning suitable actions. I also gained experience in analysing reward, steps, final distance and success rate to evaluate system performance. If redesigned, I would improve the simulation environment by introducing dynamic obstacles and multiple targets.

APPENDICES

Appendix A – Detailed Calculations

Include the calculations used in the project, such as:

1. Search Coverage

$$\text{Search Coverage} = (\text{Area searched} / \text{Total search area}) \times 100$$

2. Target Detection Rate

$$\text{Target Detection Rate} = (\text{Number of targets detected} / \text{Total number of targets}) \times 100$$

3. Q-value Update

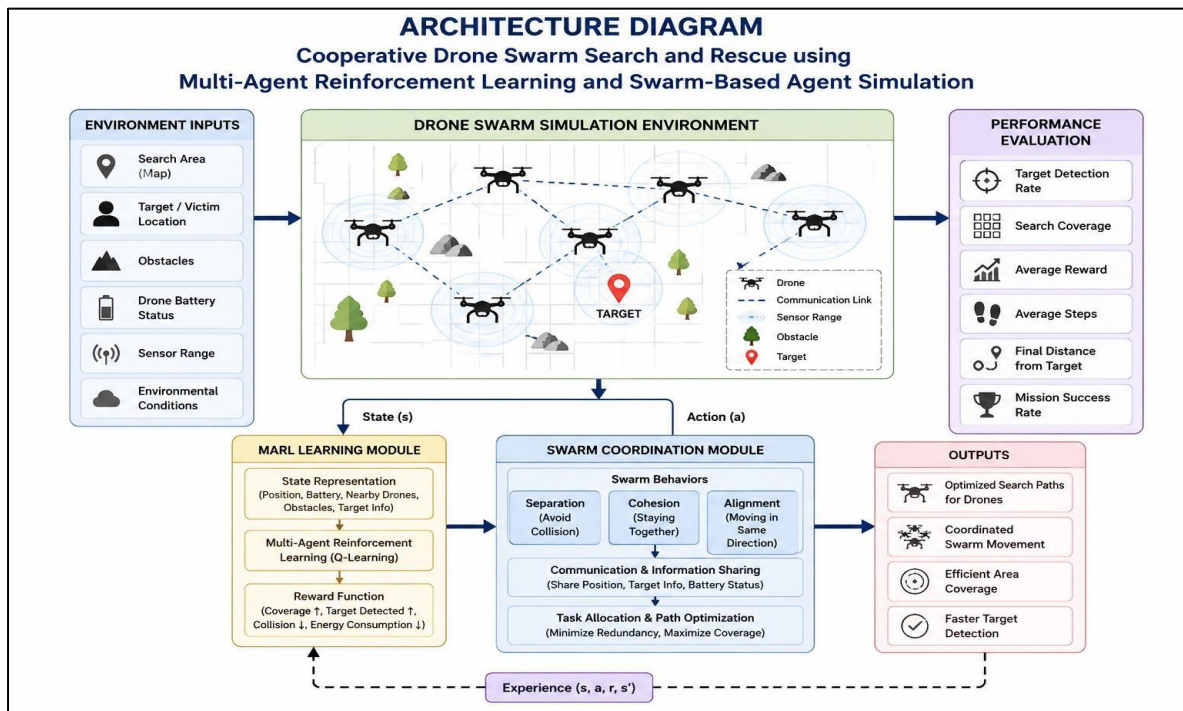

$$Q(s,a) = Q(s,a) + \alpha[R + \gamma \max_{a'} Q(s',a') - Q(s,a)]$$

Where:

- α = learning rate
- γ = discount factor
- R = reward
- s = current state
- a = current action
- s' = next state
- a' = next action

These equations are part of the documented MARL methodology.

Appendix B – Engineering Drawings / Schematics

The project source includes an architecture showing the search environment, MARL module, swarm coordination module, and performance evaluation.

Appendix C – Source Code / Code Repository Information

<https://github.com/lasya795/MLA0305-REINFORCEMENT-LEARNING/blob/main/Capstone-Project%20Horizon/Capstone-Project%20Final%20Review/app.R>

Appendix D – Datasheets

“Not applicable. The project was developed and evaluated using a simulated drone swarm environment, and no specific physical hardware datasheets were documented.”

Appendix E – Experimental / Raw Data

Drone	Battery	Speed	Target Distance	Status
Drone 1	75.18	36.03	31.06	Target Detected
Drone 2	45.26	60.95	82.45	Searching
Drone 3	51.84	40.50	47.03	Target Detected
Drone 4	38.45	80.42	32.87	Target Detected
Drone 5	46.18	71.23	12.57	Searching

The simulation used 5 drones and 50 simulation steps, with an average final distance of 3.77 and total reward of 601.12.

The reported performance results were:

- Average Reward: 217.86
- Average Steps: 15.50
- Final Distance: 0.00
- Maximum Reward: 378.18
- Success Rate: 100%

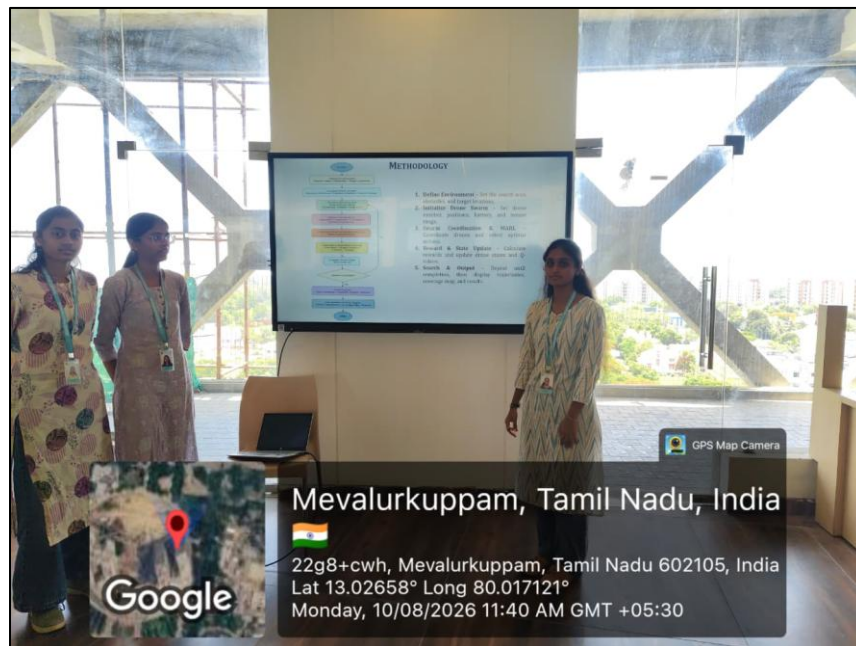

Appendix F – Ethics / Institutional Approval

The project involves the development and simulation of a cooperative drone swarm search and rescue system using Multi-Agent Reinforcement Learning (MARL) and swarm-based agent simulation. The project uses synthetic drone data and a simulated search environment for development, training, and performance evaluation. The documented work does not include any specific ethics approval or institutional approval documentation.

The project documentation states that the work was carried out in accordance with engineering ethics and academic integrity. The sources, data, results, analysis, and findings are intended to be appropriately acknowledged and reported without fabrication, falsification, or manipulation.

Appendix G – Project Meeting / Progress Records

- ☐ Generation of synthetic drone swarm data.
- ☐ Data preprocessing and normalization.
- ☐ Development of the cooperative drone swarm simulation.
- ☐ Implementation of swarm coordination using separation, cohesion and alignment.
- ☐ Development of the Multi-Agent Reinforcement Learning (MARL) model.
- ☐ Implementation of cooperative reward calculation.
- ☐ Performance evaluation using reward, search steps, final distance and success rate.
- ☐ Analysis and documentation of the obtained results.

Appendix H – User/Industry Feedback

The project focuses on developing a cooperative drone swarm system for autonomous search and rescue using Multi-Agent Reinforcement Learning (MARL) and swarm-based agent simulation. The available project report and presentation describe the system methodology, simulation, performance evaluation and results, but do not contain documented feedback from external users, industry personnel, rescue organizations, or other stakeholders.

The system was evaluated using technical performance measures including search coverage, target detection, average reward, search steps, final distance and success rate. The reported results demonstrate the effectiveness of the proposed cooperative approach within the simulated environment.

Appendix I – Publications / Patents / Competitions / Product Outcomes

The project developed a cooperative drone swarm search and rescue system using Multi-Agent

Reinforcement Learning (MARL) and swarm-based agent simulation. The project documentation presents the methodology, algorithms, simulation results, performance evaluation and future scope of the proposed system.

The available project source files do not document any completed publication, patent, competition participation or product outcome resulting from this project.

Appendix J – Individual Contribution Evidence

Student Name / Register No.	Project Contribution Area
P. Hithaishi – 192425196	Contribution to the development and documentation of the cooperative drone swarm search and rescue project
K. Sri Lasya – 192472216	Contribution to the development, analysis and documentation of the MARL and swarm-based simulation approach
N. Parnitha – 192525322	Contribution to data generation, preprocessing, performance evaluation and project documentation

The overall project work included synthetic drone swarm data generation, data preprocessing, cooperative drone simulation, swarm coordination, Multi-Agent Reinforcement Learning, cooperative reward calculation, performance evaluation and documentation of the results.
